

MIT Joint Program on the Science and Policy of Global Change

Climatology and Trends in the Forcing of the Stratospheric Ozone Transport

Erwan Monier and Bryan C. Weare

**Report No. 191
January 2011**

The MIT Joint Program on the Science and Policy of Global Change is an organization for research, independent policy analysis, and public education in global environmental change. It seeks to provide leadership in understanding scientific, economic, and ecological aspects of this difficult issue, and combining them into policy assessments that serve the needs of ongoing national and international discussions. To this end, the Program brings together an interdisciplinary group from two established research centers at MIT: the Center for Global Change Science (CGCS) and the Center for Energy and Environmental Policy Research (CEEPR). These two centers bridge many key areas of the needed intellectual work, and additional essential areas are covered by other MIT departments, by collaboration with the Ecosystems Center of the Marine Biology Laboratory (MBL) at Woods Hole, and by short- and long-term visitors to the Program. The Program involves sponsorship and active participation by industry, government, and non-profit organizations.

To inform processes of policy development and implementation, climate change research needs to focus on improving the prediction of those variables that are most relevant to economic, social, and environmental effects. In turn, the greenhouse gas and atmospheric aerosol assumptions underlying climate analysis need to be related to the economic, technological, and political forces that drive emissions, and to the results of international agreements and mitigation. Further, assessments of possible societal and ecosystem impacts, and analysis of mitigation strategies, need to be based on realistic evaluation of the uncertainties of climate science.

This report is one of a series intended to communicate research results and improve public understanding of climate issues, thereby contributing to informed debate about the climate issue, the uncertainties, and the economic and social implications of policy alternatives. Titles in the Report Series to date are listed on the inside back cover.

Climatology and Trends in the Forcing of the Stratospheric Ozone Transport

Erwan Monier* and Bryan C. Weare†

Abstract

A thorough analysis of the ozone transport was carried out using the Transformed-Mean Eulerian (TEM) tracer transport equation and the European Centre for Medium-Range Weather Forecasts (ECMWF) Re-Analysis (ERA-40). In this budget analysis, the chemical net production term, which is calculated as the residual of the other terms, displays the correct features of a chemical sink and source term, including location and seasonality, and shows a good agreement in magnitude compared to other methods of calculating ozone loss rates. This study provides further insight into the role of the eddy ozone transport and underlines its fundamental role in the recovery of the ozone hole during spring. The trend analysis reveals that the ozone hole intensification over the 1980–2001 period is not directly related to the trend in chemical losses, but more specifically to the balance in the trends in chemical losses and transport. That is because, in the SH from October to December, the large increase in the chemical destruction of ozone is balanced by an equally large trend in the eddy transport, associated with a small increase in the mean transport. This study shows that the increase in the eddy transport is characterized by more poleward ozone eddy flux by transient waves in the midlatitudes and by stationary waves in the polar region. This is primarily due to the presence of storm tracks in the midlatitudes and of the asymmetric Antarctic topography and ice-sea heating contrasts near the pole. Overall, this study makes clear of the fact that without an increase in the eddy ozone transport over the 1980–2001 period, the ozone hole over Antarctica would be drastically more severe. This underlines the need for careful diagnostics of the eddy ozone transport in modeling studies of long-term changes in stratospheric ozone.

1. INTRODUCTION

In the 1920s, chlorofluorocarbons (CFC) started replacing more toxic compounds like ammonia, chloromethane or sulfur dioxide as refrigerants as well as propellants in aerosol cans,

* MIT Joint Program on the Science and Policy of Global Change, Cambridge, MA (E-mail: emonier@mit.edu).

† Atmospheric Science Program, Department of Land, Air and Water Resources, University of California, Davis.

fire extinguishers or cleaning solvents. In 1974, CFCs were identified as the major source of ozone-destroying stratospheric chlorine (Molina and Rowland, 1974), a chemical element that was shown could engage in a catalytic cycle resulting in ozone destruction (Stolarski and Cicerone, 1974). Since then, countless observational studies have reported that the total column ozone has decreased over many regions of the globe since about 1980, with particularly severe ozone depletion over Antarctica in the spring, leading to what is now referred to as the ozone hole. Over Antarctica, extreme low temperatures during winter and early spring facilitate the formation of polar stratospheric clouds (PSCs), which support chemical reactions that produce active chlorine, which goes on to catalyze ozone destruction. The adoption of the Montreal Protocol in 1987, banning the production of CFCs and other ozone depleting chemicals, has made the ozone hole a scientific success story and was called the most successful international environmental agreement.

However, Molina and Rowland (1974) and Rowland and Molina (1975) pointed out that CFCs have very long atmospheric residence times and they would continue to deplete the stratospheric ozone well into the twenty-first century. While there has been clear evidence of a recovery since the late 1990s, this fact was well illustrated by recent observations of the 2006 ozone hole, the largest to date. As a result, the study of ozone depletion is still drawing a large interest, especially since scientists are starting to acknowledge the impact of climate change on the stratosphere. In the recent past, many observational and modeling studies have focused on the ozone variability and trend (Brunner *et al.*, 2006; Garcia *et al.*, 2007; Randel and Wu, 2007; Fischer *et al.*, 2008; Jiang *et al.*, 2008a,b). They all take advantage of the increasing high quality and diversity of models and observational datasets. The onset of comprehensive ozone and meteorological re-analysis allowed for a better analysis of the dynamics of the ozone transport in the stratosphere. While Sabutis (1997) restricted his analysis of the mean and eddy transport of ozone to the period 15 January 1979 to 10 February 1979, many subsequent studies of the dynamics of the stratospheric ozone transport were extended to larger datasets (Cordero and Kawa, 2001; Gabriel and Schmitz, 2003; Miyazaki and Iwasaki, 2005; Miyazaki *et al.*, 2005). A large effort has also been devoted to the estimation of chemical ozone loss rates from observations using various techniques such as the Match technique (Becker *et al.*, 1998; Sasano *et al.*, 2000), ozone-tracer correlations (Richard *et al.*, 2001), lagrangian transport models (Manney *et al.*, 2003) or chemical transport model passive subtraction (Feng *et al.*, 2005a,b; Singleton *et al.*, 2005, 2007). However, there is still a great deal of uncertainties in the accurate measurement of ozone chemical rate loss over large periods of time. Other areas of research include the impact of climate change on ozone (Jiang *et al.*, 2007) or more theoretical studies such as the impact of the wave- and zonal mean-ozone feedback on the stratospheric dynamics, including the quasi-biennial oscillation (QBO) (Cordero *et al.*, 1998; Cordero and Nathan, 2000) and the vertical propagation of planetary waves (Nathan and Cordero, 2007). Overall, there seems to be a lack of thorough analysis of the impact of wave-induced transport on the long-term changes in stratospheric ozone based on meteorologically consistent three-dimensional ozone datasets.

Thus the aim of this study is to investigate the role of the various dynamical forcing on the

transport of zonal-mean ozone and its long-term changes, using a thorough budget analysis of the Transformed-Mean Eulerian (TEM) formulation of the tracer transport equation with the European Centre for Medium-Range Weather Forecasts (ECMWF) Re-Analysis (ERA-40). The TEM formulation offers a useful diagnostics to interpret the forcing of the ozone transport by eddies (Andrews *et al.*, 1983). This work intends on providing a more comprehensive understanding of the contribution of planetary waves, their stationary and transient components, to the transport of ozone. Such analysis is vital as the impact of long-term changes in ozone and wave activity on the dynamics of the stratosphere is not yet fully understood.

2. DATA AND METHODOLOGY

2.1 Data

In this study we use the six-hourly ERA-40 re-analysis (Uppala *et al.*, 2005) in order to calculate the various terms involved in the Transformed Eulerian-Mean formulation of the ozone transport equation. These terms include flux quantities like the eddy flux vector and the residual mean meridional circulation. The ERA-40 was chosen because it provides a complete set of meteorological and ozone data, over the whole globe on a $2.5^\circ \times 2.5^\circ$ grid and over a long time period (1957–2001). The ERA-40 compares well with independent ground-based Dobson observations, Microwave Limb Sounder (MLS) satellite and ozonesonde data, both in total ozone and in ozone profiles (Dethof and Hólm, 2004). The ERA-40 ozone field has also been compared with Upper Atmosphere Research Satellite (UARS) and Measurements of Ozone and Water Vapour by Airbus In-Service Aircraft (MOZAIC) measurements, showing broad agreement (Oikonomou and O'Neill, 2006). The ERA-40 shows several weaknesses, such as an enhanced Brewer-Dobson circulation (van Noije *et al.*, 2004; Uppala *et al.*, 2005) and a weaker Antarctic ozone hole, and of less vertical extent, than the independent observations (Oikonomou and O'Neill, 2006). There is also the presence of vertically oscillating stratospheric temperature biases over the Arctic since 1998 and over the Antarctic during the whole period (Randel *et al.*, 2004). In addition, the pre-satellite ERA-40 data in the Southern Hemisphere (SH) stratosphere are unrealistic (Renwick, 2004; Karpetchko *et al.*, 2005). Nonetheless, the ERA-40 re-analysis provides a reasonable ozone and meteorological dataset in the lower stratosphere during the satellite era. For this reason, the climatological analysis of the wave forcing of the stratospheric ozone transport is performed over the 1980 to 2001 period and for pressure levels up to 10 hPa.

2.2 Methodology

2.2.1 Transformed Eulerian-Mean formulation

This study uses the Transformed Eulerian-Mean (TEM) formulation of the zonal-mean tracer transport equation in log-pressure and spherical coordinates in order to accurately diagnose the eddy forcing of the zonal-mean transport of stratospheric ozone. In spherical geometry, the TEM zonal-mean ozone transport equation is (based on Equation 3.72 from Brasseur and Solomon

(2005) and on Garcia and Solomon (1983)):

$$\underbrace{\frac{\partial \bar{\chi}}{\partial t}}_{\text{Ozone tendency}} = \underbrace{-\frac{\bar{v}^*}{R} \frac{\partial \bar{\chi}}{\partial \phi} - \bar{w}^* \frac{\partial \bar{\chi}}{\partial z}}_{\text{Mean ozone transport}} \underbrace{-\frac{1}{\rho_0} \nabla \cdot \vec{M}}_{\text{Eddy ozone transport}} + \underbrace{\bar{S}}_{\text{Chemical term}} \quad (1)$$

In **Equation 1** and in the following equations, χ is the ozone volume mixing ratio and \bar{v}^* , \bar{w}^* are, respectively, the horizontal and vertical components of the residual mean meridional circulation defined by (Eqs. 3.5.1a and 3.5.1b from Andrews *et al.* (1987)):

$$\bar{v}^* = \bar{v} - \frac{1}{\rho_0} \frac{\partial}{\partial z} \left(\rho_0 \frac{\overline{v'\theta'}}{\bar{\theta}_z} \right) \quad (2)$$

$$\bar{w}^* = \bar{w} + \frac{1}{a \cos \phi} \frac{\partial}{\partial \phi} \left(\cos \phi \frac{\overline{v'\theta'}}{\bar{\theta}_z} \right) \quad (3)$$

where the overbars and primes indicate respectively the zonal means and departures from the zonal mean. θ is the potential temperature, v is the meridional wind and w is the vertical wind. $\nabla \cdot \vec{M}$ is the divergence of the eddy flux vector and represents the eddy transport of ozone. The eddy flux vector \vec{M} is written as:

$$\vec{M}^{(\phi)} = \rho_0 \left(\overline{v'\chi'} - \frac{\overline{v'\theta'}}{\bar{\theta}_z} \frac{\partial \bar{\chi}}{\partial z} \right) \quad (4)$$

$$\vec{M}^{(z)} = \rho_0 \left(\overline{w'\chi'} + \frac{1}{a} \frac{\overline{v'\theta'}}{\bar{\theta}_z} \frac{\partial \bar{\chi}}{\partial \phi} \right) \quad (5)$$

Finally, \bar{S} is the chemical net production term, which is calculated as the residual of the other terms.

Dunkerton (1978) showed that the Brewer-Dobson circulation should be interpreted as a Lagrangian mean circulation and could be approximated by the residual mean meridional circulation of the TEM equations. Thus the various processes influencing the evolution of the zonal-mean ozone that are investigated in this study are separated into three categories: the ozone production due to the advection of ozone by the Brewer-Dobson circulation or mean ozone transport, the ozone production due to the large-scale eddy transport, diagnosed by the divergence of the eddy flux vector, and the chemical net production term. The signs shown in Equation 1 are included in the various displayed terms. Each term is calculated using the six-hourly ERA-40 dataset. In addition, this formulation only allows for the calculation of the resolved eddies (dominated by planetary waves) and we do not attempt to parameterize the eddy flux divergence due to small-scale disturbances, such as gravity waves, using diffusion coefficients as described in Garcia and Solomon (1983) due to a lack of observations to evaluate such coefficients. Therefore, any contribution from the gravity waves to the eddy flux divergence would be included in the residual term. For this reason, the residual term can only be an approximation of the net chemical production term. Finally, all derivatives are computed using centered finite differences.

2.2.2 Stationary and Transient Components

Because both mean and eddy ozone transport are primarily driven by planetary waves, whether directly or indirectly, it is useful to decompose the ozone transport forcing into contributions from stationary and transient waves. Stationary planetary waves are excited by the orography (Charney and Eliassen, 1949), especially in the NH, as well as by land-sea heating contrasts, which vary on the season time scale. Planetary transient waves, on the other hand, have smaller time scales ranging from a few days to a couple weeks and dominate synoptic weather patterns. The stationary components are computed by averaging temperature, wind and ozone fields over a month and then calculating the various terms of the TEM formulation. Once the stationary component is removed from the total term, which is calculated every six hours, only the contribution from the transient waves is left (Madden and Labitzke, 1981).

3. CLIMATOLOGY OF THE STRATOSPHERIC ZONAL-MEAN OZONE TRANSPORT

3.1 Seasonal cycle of the ozone transport budget

Using Equation 1, we can separate the changes in ozone into contributions from the mean transport, the eddy transport and the chemical net production. **Figure 1** shows the seasonal cycle of the zonal-mean ozone tendency, its forcing terms and the ozone mixing ratio averaged between 100 and 20 hPa (the layer where the largest concentrations of stratospheric ozone are found). The zonal-mean ozone mixing ratio has its largest values in the Northern Hemisphere high latitudes during spring with a minimum in late summer and early fall. The lowest quantities of ozone are found in the Southern Hemisphere polar region during the austral late summer and early spring and are associated with the ozone hole. The ozone tendency shows that the largest changes in ozone occur in the polar regions. In the Northern Hemisphere, there is a clear seasonal cycle in the ozone tendency with a distinct increase in ozone at high latitudes during the fall and winter and a decrease in the spring and early summer. The ozone tendency shows the complex development and decay of the SH ozone hole with a rapid decrease in July, August and September. This is followed by a strong increase in October and November and a weaker decrease in December and January.

The mean transport of ozone is characterized by a net decrease in ozone in the tropics that is relatively uniform in time. In the polar regions, the mean transport generally results in a net increase in ozone, thus indicating the direct poleward transport of the Brewer-Dobson circulation. However, the ozone mean transport is very different between the two hemispheres. At high latitudes, the mean transport presents a pronounced seasonal cycle in the NH but it is weaker in the SH over the whole year, except for a peak in October and November. In the NH summer, the net production of ozone due to the mean transport is small in the midlatitudes and polar region because the Brewer-Dobson circulation is at its weakest (Monier and Weare, 2010). In the SH, the ozone mean transport is weak during the austral winter because ozone cannot be advected across the stratospheric polar night jet, which is much stronger than in the NH. In the spring, the intense planetary wave activity drives a strong Brewer-Dobson circulation and induces the breakdown of the polar vortex. This enables the advection of ozone-rich air from the lower latitudes into the

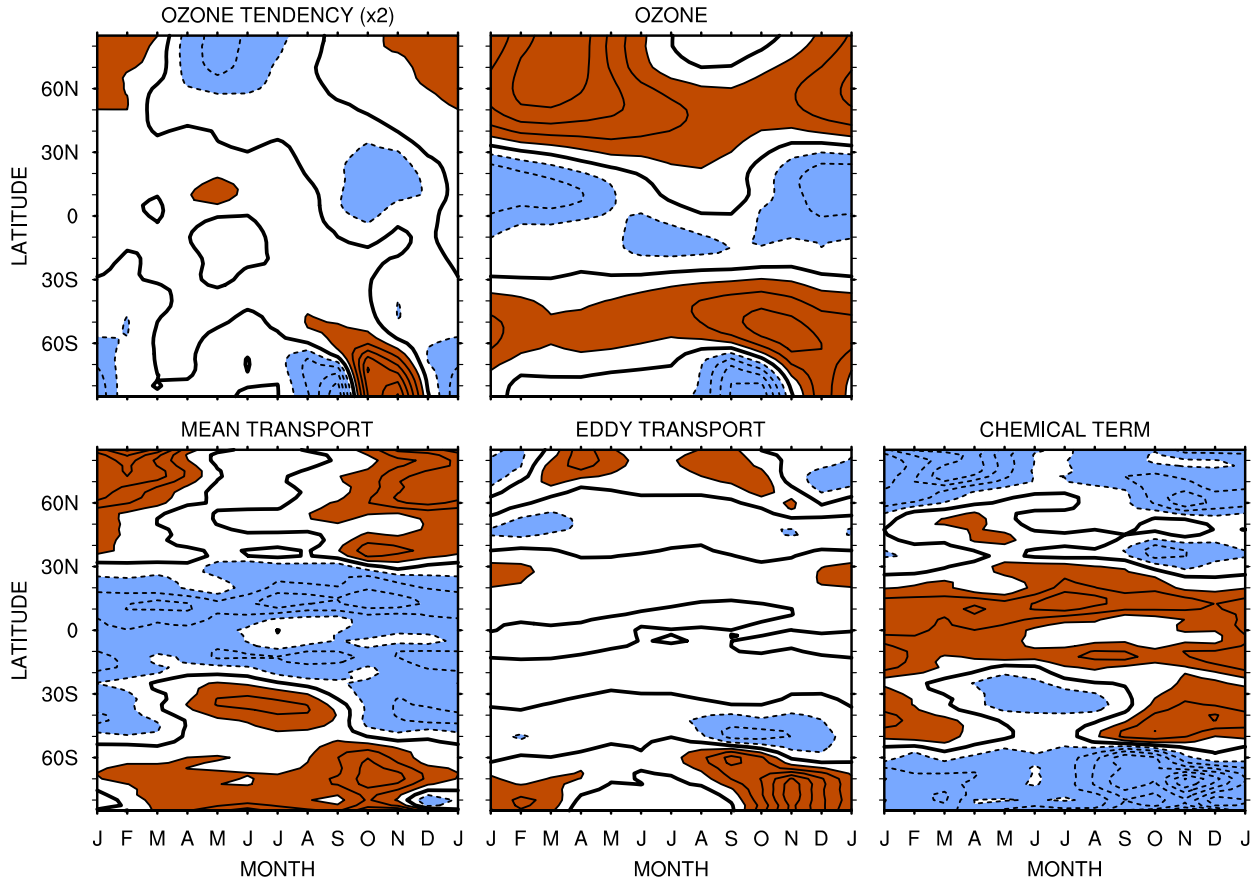

Figure 1. Annual cycle of the zonal-mean ozone, represented by the departures from the global mean (2 ppmv), and of the zonal-mean ozone tendency and its forcing terms, averaged between 100 and 20 hPa. Dashed (solid) lines and blue (brown) colors represent negative (positive) values while the bold solid line represents the zero-line. Contour spacing is 0.2 ppmv for the ozone and 10 ppbv day⁻¹ for the ozone tendency and its forcing terms. Note that the ozone tendency is weak compared to its forcing terms and is therefore multiplied by 2.

polar region, resulting in the maximum production of ozone by the mean transport. However, this is short-lived as the Brewer-Dobson circulation becomes weaker and reaches a minimum in January (Monier and Weare, 2010).

The eddy transport term is mostly positive in the tropics, except right along the Equator where it is negative, and negative in the midlatitudes. In the SH polar region, the net production of ozone by the eddy mixing is positive during spring and winter, with a maximum in November, which is the month of strongest positive ozone tendency. This corresponds to the timing of the polar vortex breakdown and the largest meridional gradient of ozone, south of 60°S. The wave activity excites mixing between ozone-poor air near the pole and ozone-rich air from the midlatitudes, resulting in a large production of ozone in the polar region. Thus, the strength of the eddy transport is strongly dependent on not only wave activity but also on the presence of a strong meridional ozone gradient. In the NH, the contribution of the eddy transport is smaller, mainly because the absence of an ozone hole during the late winter and spring provides for a weak meridional

gradient of ozone in the midlatitudes and polar region. Thus the maximum net production of ozone by eddy transport, which occurs in April, is half the magnitude of that of the SH.

Finally, the chemical term shows a net chemical production in the tropics, extending in the midlatitudes in each hemisphere during spring. The creation of ozone in the tropical stratosphere is through photodissociation of molecular oxygen by ultraviolet radiation and a subsequent reaction of the oxygen atoms with molecular oxygen in the presence of a catalyst (Brasseur and Solomon, 2005). In the polar regions, the chemical term is consistently negative. The greatest ozone destruction occurs in the springtime, with maxima in April and November in the NH and SH respectively. In the SH spring, the mean ozone chemical loss rates of the 100–20 hPa layer can reach up to 60 ppbv day⁻¹ (or ~2.5 DU day⁻¹). This is about one and a half time more than its counterpart in the NH spring. These results are consistent with previous studies. For example, chemical loss rates of ozone lower-stratosphere partial column (350 to 660 K or about 200 to 25 hPa) in the Antarctic polar region can range from 1.5 to 2.5 DU day⁻¹ in September 2000 and 2002 (Feng *et al.*, 2005b). In the NH polar region, these rates range between 0.5 and 1.2 DU day⁻¹ for February and March 2000, 2003 and 2004 (Feng *et al.*, 2005a). Similarly, Sasano *et al.* (2000) show chemical loss rates inside the Arctic polar vortex around 40 ppbv day⁻¹ from 400 to 550 K (~150 to ~50 hPa) in March 1997. This is consistent with the chemical loss rates inside the Arctic polar vortex of around 40 ppbv day⁻¹ at 450 K (~100 hPa) in late February early March 2000 from Richard *et al.* (2001).

Overall, Figure 1 shows that the strong poleward advection of ozone by the Brewer-Dobson circulation in the NH fall and winter is responsible for the positive ozone tendency at high latitudes. On the other, the weak mean ozone transport in the SH wintertime along with the chemical destruction of ozone in the polar region explain the negative ozone tendency in August and September that lead to the ozone hole. In addition, Figure 1 shows that eddy transport is largely responsible for the positive ozone tendency in the SH polar region in October and November and hence contributes to the recovery of the Antarctic ozone hole in the late spring. This is consistent with the findings of Miyazaki *et al.* (2005) who estimate that the eddy transport represents more than 80% of the total ozone transport (advective + eddy) in the Southern Hemisphere polar region in November. In addition, November is the month where the Eliassen-Palm (EP) flux divergence shows the largest values in the region, indicating the most intense planetary wave activity and the break-down of the polar vortex (Monier and Weare, 2010). Therefore, there is a self-consistency between the seasonal variability of the EP flux divergence and the eddy flux divergence in the SH. Finally, the main characteristics of the seasonal variability of the chemical production and destruction of ozone are reproduced. Furthermore, the chemical loss rates in both the Arctic and Antarctic polar regions are in reasonable agreement with previous studies. This gives confidence in the calculation of the chemical term as a residual of the ozone transport budget.

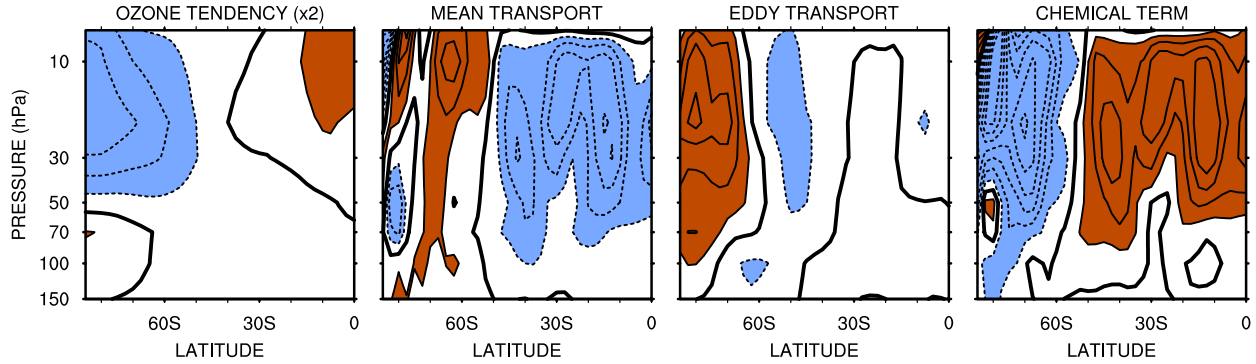

Figure 2. Zonal-mean ozone tendency and its forcing terms averaged over DJF 1980-2001 in the SH. Dashed (solid) lines and blue (brown) colors represent negative (positive) values while the bold solid line represents the zero-line. Contour spacing is 10 ppbv day^{-1} . Note that the ozone tendency is weak compared to its forcing terms and is therefore multiplied by 2.

3.2 Vertical structure of the ozone transport budget

An example of the vertical structure of the various ozone forcing, for the months of December–January–February (DJF) in the SH, is shown in **Figure 2**. The ozone tendency shows a distinct maximum decrease in the polar region centered at 20 hPa. The vertical structure of each forcing reveals that they are reasonably uniform with height, even though the mean transport exhibits some noise poleward of 80°S . All the forcing terms have the largest values between the 50 and 10 hPa levels. They also tend to show a dipole pattern with opposite effects between the polar region and the midlatitudes. The mean and eddy transports both contribute to a net production of ozone in the polar region and oppose the chemical destruction. In the tropics, where the eddy transport and the ozone tendency are weak, the chemical net production offsets exactly the mean transport of ozone by the Brewer-Dobson circulation. The chemical term shows destruction of polar ozone, with maximum values of 70 ppbv day^{-1} centered at 20 hPa and production in the tropics all the way to 50°S , with maximum values of 40 ppbv day^{-1} centered between 30 and 20 hPa. The distribution of the chemical term is in good agreement with the chemical transport model used in (Miyazaki and Iwasaki, 2005). Additionally, (Miyazaki and Iwasaki, 2005) find chemical loss rates for DJF of up to $7.5 \times 10^{10} \text{ cm}^{-3} \text{ day}^{-1}$ centered at 30 hPa in the polar region (about 80 ppbv day^{-1}) and chemical production rates up to $3 \times 10^{10} \text{ cm}^{-3} \text{ day}^{-1}$ at the same height in the tropics (about 30 ppbv day^{-1}). Thus, there is further evidence that the distribution and the magnitude of the chemical term compare well with previous studies using chemical models, chemical transport model passive subtraction and other methods based on observations.

3.3 Mean transport

The contributions of the horizontal and vertical transport to the mean ozone transport can be assessed from the analysis of the ozone mass stream function associated with the residual mean meridional circulation shown in **Figure 3**. The ozone mass stream function shows that the mean ozone transport follows the transport description proposed by Brewer-Dobson with upward

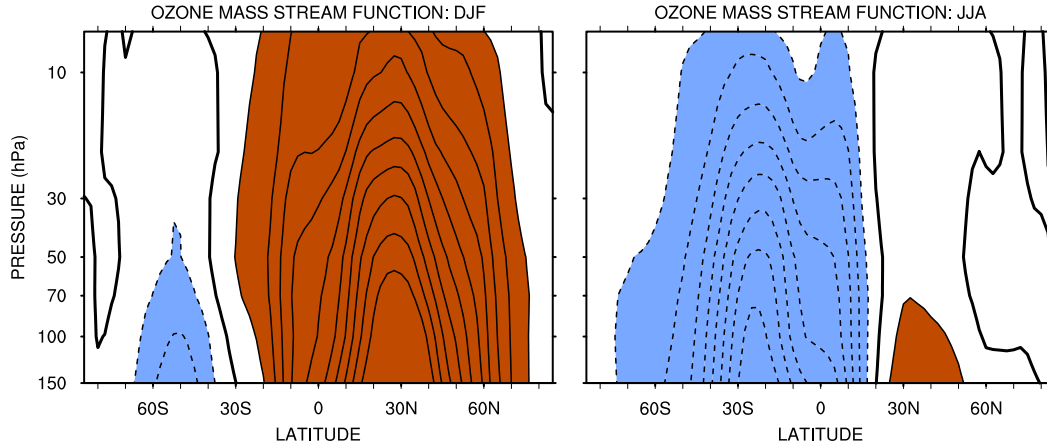

Figure 3. Ozone mass stream function associated with the Brewer-Dobson circulation averaged over (left) DJF and (right) JJA 1980-2001. Blue (brown) colors with dashed (solid) white lines represent negative (positive) values while the bold solid line represents the zero-line. Contour spacing is 10^3 kg s^{-1} .

motions in the tropics and extratropical downward motions, associated with poleward motions. The ozone mass stream function presents a distinct seasonal cycle with maximum poleward transport in each hemisphere during their respective winter. This is consistent with the annual cycle of the mean ozone transport term in Figure 1 and with other similar studies (Miyazaki and Iwasaki, 2005).

3.4 Eddy transport

In order to better understand the origins of the eddy transport term, the horizontal and vertical eddy transport terms are evaluated along with the eddy flux vector, and separated into stationary and transient components. A conspicuous feature revealed by **Figure 4** is that the eddy transport is controlled by its horizontal component as the vertical eddy transport is weak over the whole hemisphere. This is consistent with the assumption that eddy transport is primarily due to meridional mixing processes, which has been adopted in several studies (Tung, 1986; Newman *et al.*, 1988; Gabriel and Schmitz, 2003). In addition, the eddy transport is provided about equally by stationary and transient waves, with the transient eddy transport dominating only slightly in the midlatitudes. This is consistent with the findings from Monier and Weare (2010) looking at planetary wave activity in the SH diagnosed by the Eliassen-Palm (EP) flux divergence.

The components of the eddy flux vector represent the horizontal and vertical flux of ozone eddies by the wave components of the wind velocities. In comparison, the eddy flux divergence corresponds to the net ozone transport in a specific region due to the net ozone eddy flux entering this region. In the SH spring, the vertical eddy ozone flux is upward in the midlatitudes and near the pole and downward in the subpolar region. Meanwhile, the horizontal eddy ozone flux is composed of poleward transport in the polar region and equatorward transport in the midlatitudes and subtropics. The fact that the horizontal ozone eddy flux is three orders of magnitude greater than its vertical counterpart explains its major role in the eddy transport.

The eddy ozone transport is dominated by transient processes in the midlatitudes due to high

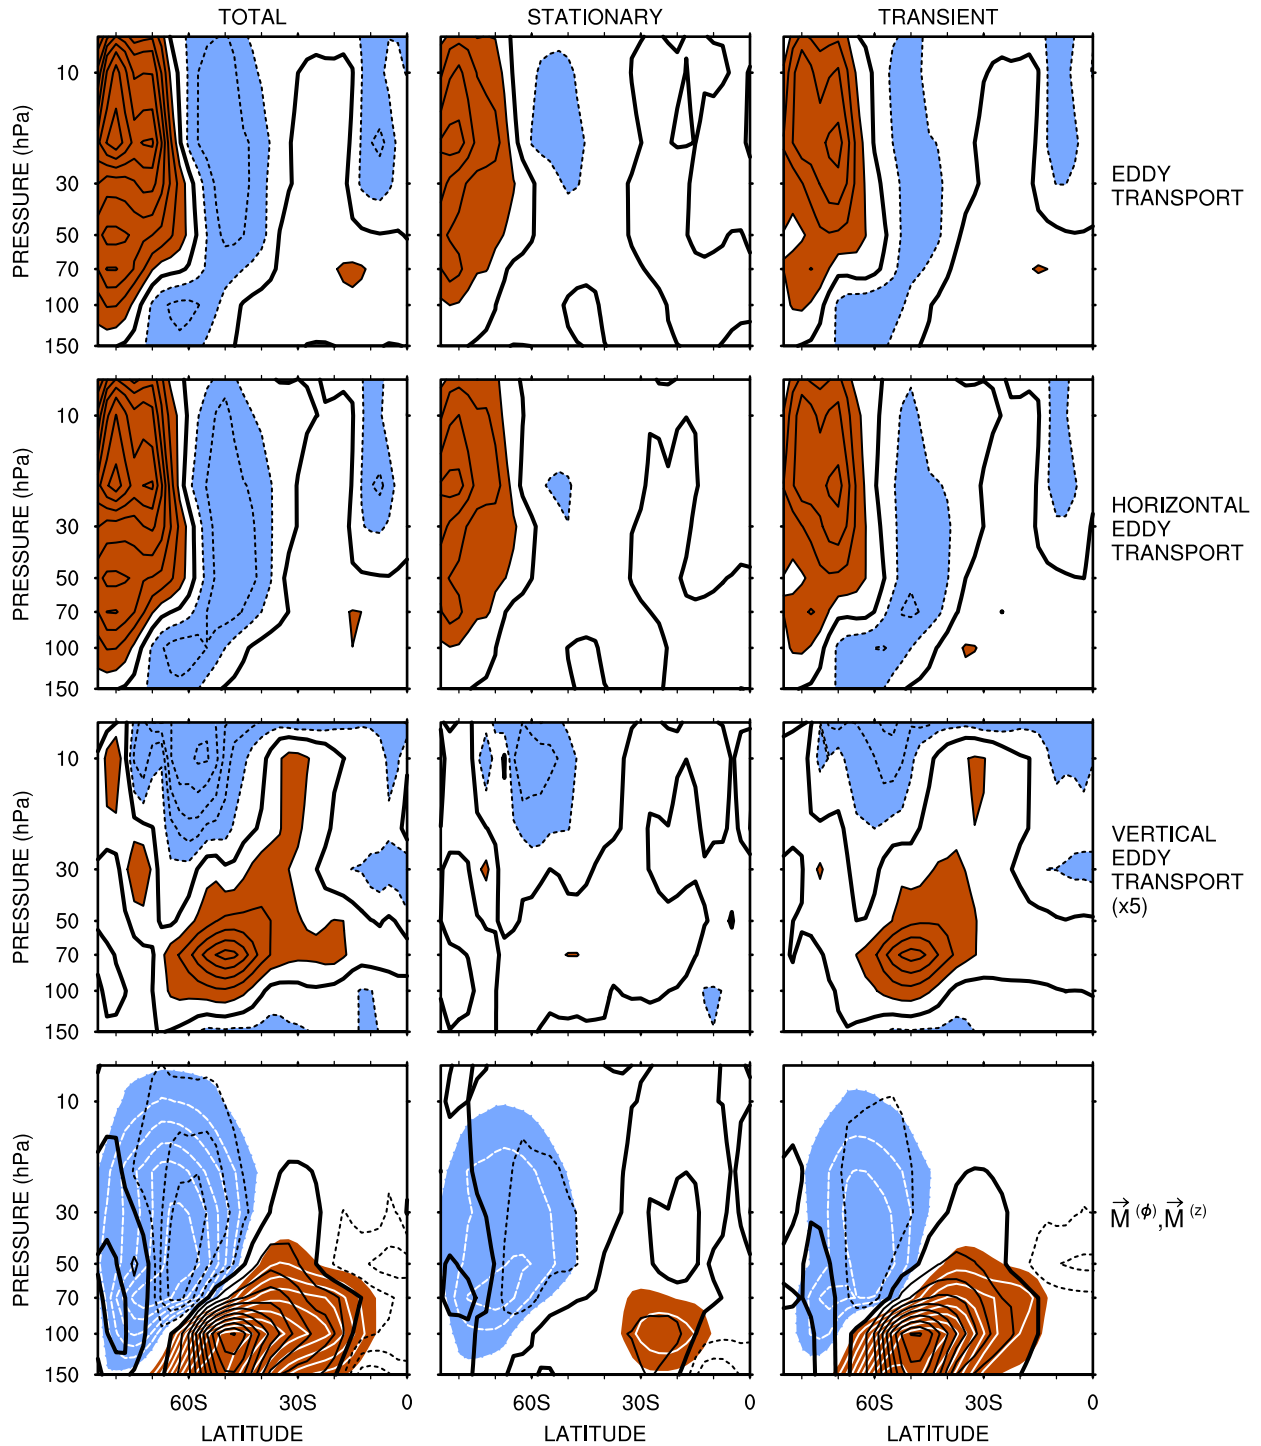

Figure 4. Same as Figure 2 but for the eddy ozone transport, its horizontal and vertical components, and the eddy ux vector, with the contributions of stationary and transient waves. Blue (brown) colors with dashed (solid) white lines represent negative (positive) values for $\vec{M}^{(\phi)}$. Dashed (solid) black lines represent negative (positive) values while the bold solid line represents the zero-line for $\vec{M}^{(z)}$. Contour spacing is 10 ppbv day^{-1} for the eddy transport and its horizontal and vertical components, $2 \times 10^5 \text{ kg ppbv m}^{-2} \text{ day}^{-1}$ for $\vec{M}^{(\phi)}$ and $2 \times 10^2 \text{ kg ppbv m}^{-2} \text{ day}^{-1}$ for $\vec{M}^{(z)}$. Note that the vertical eddy transport is weak compared to the horizontal eddy transport and is therefore multiplied by 5.

transient wave activity associated with storm tracks located near 50°S throughout the year (Trenberth, 1991). However, the stationary eddy transport is stronger than the transient eddy transport in the polar region. This can be explained by the presence of the asymmetric Antarctic topography and ice-sea heating contrasts driving the stationary wave activity in the polar region, as it has been demonstrated in several studies (Parish *et al.*, 1994; Lachlan-Cope *et al.*, 2001).

4. TRENDS IN THE WAVE FORCING OF THE STRATOSPHERIC ZONAL-MEAN OZONE TRANSPORT

4.1 Zonal-mean ozone

The long-term trends and interannual variability of the lower and middle stratosphere (LMS) ozone are investigated in **Figure 5**. The variances and trends are calculated after the zonal-mean ozone is averaged between 100 and 20 hPa. The ozone variance, representing its interannual variability, is large in the polar region in both hemispheres during their respective late winter and early spring. A weaker variance maximum is also present in the tropics, most likely related to the Quasi-Biennial Oscillation (QBO). In the SH, the year-to-year variability of the LMS zonal-mean ozone layer is associated with the ozone hole and located south of 60°S. The maximum ozone trends associated with the Antarctic ozone hole occur in September at a rate above 0.5 ppmv per decade, with a 99.9% statistical significance level (calculated using a Student's t-test). There is also a negative ozone trend in the NH polar region during spring that corresponds to a decrease of the ozone maximum that occurs at that time. In March, the NH polar ozone has decreased between 1980 and 2001 at a rate of over 0.2 ppmv per decade, with a 93% statistical significance

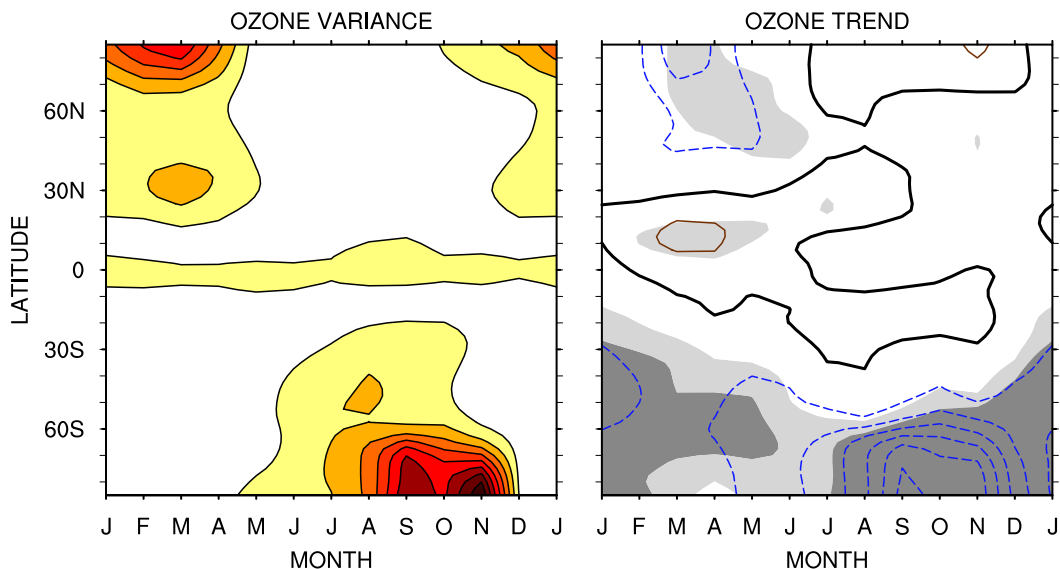

Figure 5. Annual cycle of the ozone sample variance and trend. The variances and trends are calculated after the zonal-mean ozone is averaged between 100 and 20 hPa. Dashed blue (solid brown) lines represent negative (positive) values while the bold solid line represents the zero-line. Light grey (dark grey) shading represents the 90% (99%) statistical significance level of the trends. Contour spacing is 0.05 ppmv² for the ozone variance and 0.1 ppmv per decade for the ozone trend.

level. The long-term changes in the polar ozone work out to be a decrease of $\sim -10\%$ over 22 years in the NH in March and of $\sim -40\%$ in the SH in September. This is consistent with Brunner *et al.* (2006), using the Candidoz Assimilated Three-dimensional Ozone (CATO) multiple linear regression model, who find maximum negative trends north of 60°N in February and March at about -5% per decade, and a maximum trend in the SH polar region in October, close to -20% per decade, from 1979–2004. Moreover, the seasonality of the trends is consistent with previous modeling and observational studies. Randel and Wu (2007) calculated seasonal variations of the trends in the vertically integrated ozone column derived from analysis of Stratospheric Aerosol and Gas Experiment (SAGE I and II) profile measurements, combined with polar ozonesonde data. They found a maximum trend in the polar region over the 1979 to 2005 time period in the NH April and SH October. Meanwhile, Garcia *et al.* (2007) provide a similar analysis based on the Whole-Atmosphere Community Climate Model (WACCM) column of ozone. They show maximum trends in the polar region from 1979 to 2003 in the NH February and SH October. Thus there is some uncertainty as to which month displays the maximum trends, but an overall agreement over the seasonality of the trends in the stratospheric polar ozone.

4.2 Wave forcing ozone budget

Figure 6 shows the annual cycle of the linear trends of the ozone tendency and its forcing terms over 1980–2001. In the SH, the largest and most significant trends occur from September to December and show that negative trends in the chemical losses are largely balanced by positive trends in the eddy transport, apparently following by a month. Meanwhile, the trends in the ozone mean transport are weaker and not statistically significant (except for the month of December).

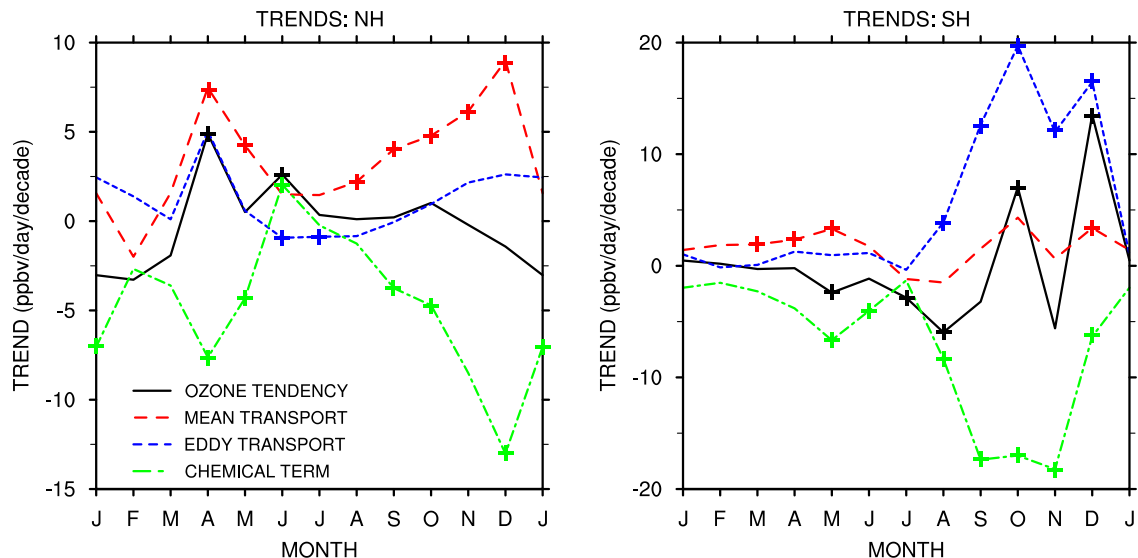

Figure 6. Annual cycle of the trends in the ozone tendency and its forcing terms, for the (left) NH and the (right) SH. The trends are calculated after the zonal-mean ozone tendency and its forcing terms are averaged between 100 and 20 hPa and between 60° – 85° . Trends that are statistically significant at the 95% statistical significance level are indicated by a cross.

The timing of the trends in the ozone chemical destruction corresponds to the ozone hole, when the polar region is the coldest due to a lack of radiative heating by ozone. When the region is very cold, PSCs can form thus inducing even more chemical destruction. Because the strength of the eddy transport is strongly dependent on not only wave breaking activity but also on the presence of a strong meridional ozone gradient, the destabilization of the ozone layer over the Antarctica leads to an increase in the spring eddy transport. As the ozone hole grows stronger year after year, so does the meridional ozone gradient. This leads to more mixing, near the edge of the polar vortex, between rich and poor regions of ozone. This explains why the trends in the eddy transport lag by one month the trends in the chemical term. It is worthy to note that the dip in the eddy flux divergence in November coincides with a weakening of the planetary wave activity, as it is revealed from the trend analysis of the EP flux divergence in Monier and Weare (2010). Hence, the trends in the eddy flux divergence might be controlled not only by the variations in the meridional ozone gradient but also by the long-term changes in wave activity. The weakening of the planetary wave activity can also explain the similar dip in the ozone mean transport trends during the month of November, since the long-term weakening of the planetary wave activity is accompanied by a weakening of the Brewer-Dobson circulation.

In August, the strength of the polar night jet is at its maximum and it acts as an eddy mixing barrier (Haynes and Shuckburgh, 2000; Miyazaki *et al.*, 2005). Additionally, the meridional gradient of ozone is weak at the time. As a result, the trend in the eddy ozone transport remains weak, much weaker than between September and December. Consequently, the negative trend in the chemical destruction of ozone in August, which is significantly weaker than from September to November, remains unbalanced by trends in the ozone transport. This leads to a significantly negative trend in the ozone tendency in August, which in turn is responsible for the maximum ozone trend over Antarctica that occurs in September. Thus the ozone hole intensification over 1980–2001 time period is not directly related to the trend in chemical losses, but more specifically to the balance in the trends in chemical losses and ozone transport.

The balance between the trends in the ozone forcing terms results in month-to-month changes in the trend in the ozone tendency. Figure 6 shows that the only statistically significant trends in the ozone tendency are negative in May, July and August (leading to the intensification of the ozone hole) and positive in October in December (leading to the intensification of the ozone hole recovery in late spring).

In the NH, the picture is more complicated, mainly due to the absence of strong polar ozone depletion and the associated meridional gradient of ozone. Overall, the negative trends in the chemical losses are balanced primarily by the positive trends in the ozone mean transport, and not the eddy transport as in the SH, apparently at zero lag. However, the trends are much weaker than in the SH. Two particular months show distinct balances in the trends of the ozone tendency forcings. In April, increases in the mean and eddy ozone transport balance a significant increase in the ozone chemical destruction. This results is consistent with the analysis of the trends of the stratospheric wave forcing in Monier and Weare (2010) who show a delay of the polar vortex break-down and an increase in the planetary wave activity in April in the NH, associated with an

intensification of the Brewer-Dobson circulation. The delay in the break-down of the polar vortex can result in sustained cold temperature in April, thus extending the period of ozone chemical destruction and leading to an increase in the chemical term in April. In December, a large positive significant trend in the mean ozone transport is mirrored by a large negative significant trend in the chemical term. However, an explanation for this behavior is not clear. In the polar region, the mean ozone transport is controlled by its downward descent. Hence, the trend in the mean transport can be influenced by long-term changes in both the vertical branch of the Brewer-Dobson circulation and the vertical gradient of ozone. It is therefore possible that changes in the vertical profile of ozone are responsible for the large positive trend in the mean transport of ozone in December. Since the eddy transport is weaker than the other forcing terms in the NH, it is expected that the chemical term would largely balance the mean transport term. This would lead to a large intensification of the chemical destruction in December that cannot be easily explained either.

Figure 7 shows latitude-height cross-sections of the trends in the ozone tendency and its forcing terms for the months of October-November-December (OND) in the SH. The ozone tendency shows a significant positive trend in the polar region centered at 30 hPa. The trends in the ozone forcing terms are noisier, particularly for the mean ozone transport, but show distinct patterns. Both mean and eddy transport present positive trends in the polar regions and negative trends at midlatitudes centered at 20 hPa, in opposition to that of the chemical term. These trends reveal an intensification of the dipole pattern of ozone forcing showed in Figure 1, as in OND both mean and eddy transport terms contribute to increasing ozone in the polar region and decreasing it in the midlatitudes. The trends in the eddy transport are stronger than that of the mean transport, which is consistent with the results shown in Figure 6. In the SH springtime (OND), the trends in the eddy ozone transport reach a maximum of 80 ppbv day^{-1} per decade at 20 hPa in the polar region over the 1980–2001 period. As a comparison, the mean eddy ozone transport at the same location and over the same time period is $100 \text{ ppbv day}^{-1}$. This reveals a very large increase in the eddy transport from 1980 to 2001 in the stratospheric polar region over Antarctica.

Figure 8 shows the SH latitude-height cross-sections of the OND trends in the eddy ozone transport and the horizontal component of the eddy flux vector, with the contributions of stationary and transient waves. Figure 8 reveals that the trends in the eddy transport are present in both its stationary and transient components. The trend in the eddy flux vector indicates a bias toward stronger poleward eddy mixing above 50 hPa in the polar region and midlatitudes, most likely due to a stronger meridional ozone gradient caused by the ozone hole. The trend in the midlatitudes is dominated by transient wave activity, corresponding to the location of storm tracks, while the contribution of stationary waves is limited to the polar region, likely associated with the presence of the asymmetric Antarctic topography and ice-sea heating contrasts. The fact that the trends are similar between the stationary and transient components of the eddy ozone transport and that their main differences (their latitudinal location) can be physically explained gives credibility to these results.

5. CONCLUSIONS

A thorough analysis of the ozone transport was carried out using the TEM tracer transport equation with the ERA-40 re-analysis. The resolved terms in the ozone transport equation are the ozone tendency, the mean ozone transport by the Brewer-Dobson circulation and the eddy ozone transport. In addition, the residual term in the TEM ozone transport equation is shown to be representative of the chemical net production term. This is an approximation since it does also contain ozone transport due to unresolved waves, such as gravity waves. However, the chemical term displays the correct features of a chemical sink and source term, including location and seasonality, and shows a good agreement in magnitude compared to other methods of calculating ozone loss rates. This provides reasonable confidence in the ozone transport budget calculated in this study. Thus, we assume that the contribution from gravity waves is negligible compared to the chemical term, which should be especially true in the polar region and tropics where chemical rates of destruction and production are large. Furthermore, the climatology of both the mean and eddy transports is consistent with previous studies (Miyazaki and Iwasaki, 2005; Miyazaki *et al.*, 2005) using independent datasets. Consequently, the ozone budget based on the TEM tracer transport equation presented in this study provides a reasonable method to investigate the dynamical and chemical ozone forcing over the whole globe and over long time periods using re-analysis datasets.

In the wintertime, the transport of ozone from the tropics to the polar regions is primarily controlled by the transport of ozone by the Brewer-Dobson circulation, which is stronger in the NH because the SH polar night jet is strong enough to suppress the transport of ozone across the subpolar region (Miyazaki *et al.*, 2005). The ozone advection reaches a maximum in the late winter and early spring, when intense planetary wave activity drives a stronger Brewer-Dobson circulation and induces the breakdown of the polar vortex. In spring, the eddy transport is responsible for a net production of ozone in the polar region, especially in the SH where the eddy transport is so large it balances a large fraction of the chemical ozone destruction. Therefore, this

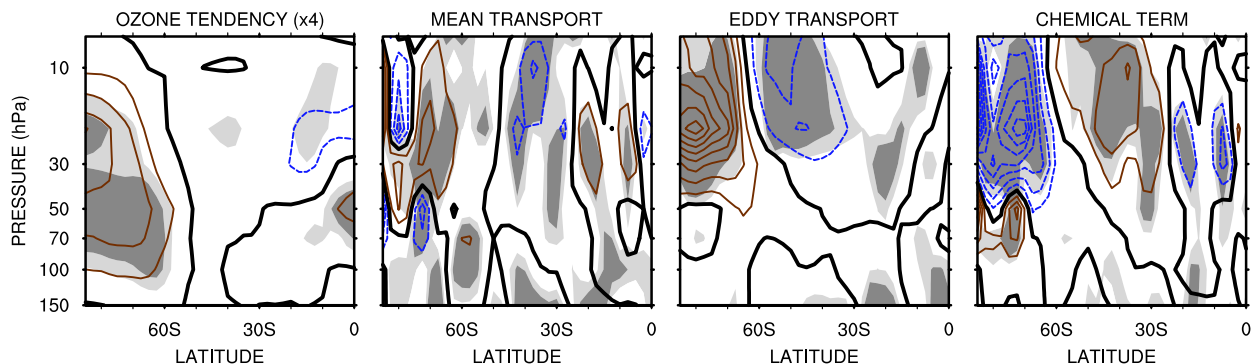

Figure 7. OND trends in the ozone tendency and its forcing terms for the SH. Dashed blue (solid brown) lines represent negative (positive) values while the bold solid line represents the zero-line. Light grey (dark grey) shading represents the 95% (99%) statistical significance level of the trends. Contour spacing is 10 ppbv day^{-1} per decade. Note that the trends in the ozone tendency are weak compared to the forcings terms and are therefore multiplied by 4.

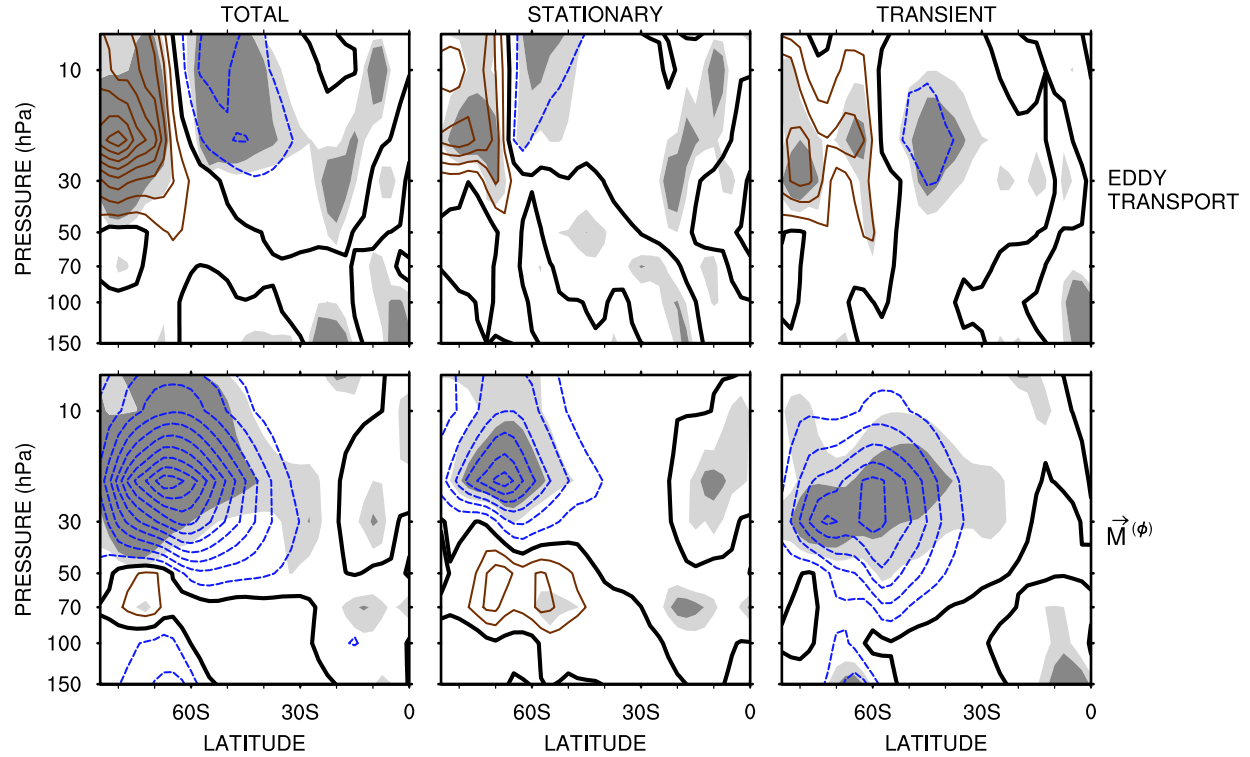

Figure 8. Same as Figure 7 but for the eddy ozone transport and the horizontal component of the eddy ux vector, with the contributions of stationary and transient waves. Contour spacing is 10 ppbv day^{-1} per decade for the eddy transport and $2 \times 10^5 \text{ kg ppbv m}^{-2} \text{ day}^{-1}$ per decade for $\vec{M}^{(\phi)}$.

study outlines the considerable contribution of eddy mixing to the overall transport of ozone in the SH. This is consistent with previous theoretical and observational studies (Muller *et al.*, 2005; Manney *et al.*, 2006). The chemical term shows a net chemical production in the tropics, extending in the midlatitudes in each hemisphere during spring. In the polar regions, the chemical term is consistently negative. The greatest ozone destruction occurs in the springtime, with maxima in April and November in the NH and SH respectively. This analysis clarifies the role of eddy transport in the recovery of the Antarctic ozone hole in the late spring. At the time, the meridional gradient of ozone is large and the polar vortex is breaking down leading to horizontal mixing across the subpolar region between ozone-rich and ozone-poor regions.

The trend analysis reveals that the largest intensification of the ozone chemical destruction coincides with the timing of the Antarctic ozone hole, from September to November. However, these trends are balanced by equally large positive trends in the eddy transport, associated with a small increase in the mean transport. As a result, the trends in the ozone tendency over Antarctica tend to be positive during that period and immediately following it, leading to an intensification of the springtime recovery of the ozone hole. On the other hand, a weaker intensification of the ozone chemical destruction occurs in August and remains unchallenged by trends in the ozone transport. Consequently, the trend in the ozone tendency is significantly negative in August. This leads to the maximum ozone trend in September over Antarctica associated with the ozone hole.

In other words, the intensification of the ozone hole is not directly related to the largest trends in the chemical destruction, but more specifically to the complex balance in the trends in chemical losses and ozone transport. In August, the trend in the eddy ozone transport is weak because the strength of the polar night jet is at its maximum and it acts as an eddy mixing barrier, and because the meridional gradient of ozone remains weak. The increase in the spring eddy transport is caused by an intensification of the meridional gradient of ozone associated with the enhancement of the ozone hole. The mixing between ozone-rich and ozone-poor regions near the edge of the polar vortex increases as a result. This is corroborated by statistically significant trends showing a tendency for stronger horizontal eddy transport from the subtropics to the pole. Transient waves are responsible for most of the trends in the midlatitudes while the contribution of stationary waves is mainly limited to the polar region. The increase in the eddy transport presents a distinct dip in November, corresponding to a decrease in planetary wave activity identified in Monier and Weare (2010). This demonstrates that the eddy transport is not only controlled by the meridional ozone gradient, but is also impacted by changes in the planetary wave activity during the polar vortex breakdown. Overall, the increase in the eddy transport overcomes the intensification of the chemical destruction in October and November and provides the fundamental mechanism for the ozone recovery in the late spring. This study also shows that without an increase in the eddy transport over the 1980–2001 time period, the ozone hole over Antarctica would be drastically more severe.

This work suggests that modeling studies investigating trends in stratospheric ozone, especially over Antarctica, should pay a great deal of attention to the simulation of the eddy ozone transport and the dynamics of the stratosphere. In particular, trends in the dynamical transport of ozone have a significant impact on the overall long-term ozone budget. It appears obvious that diagnostics of the eddy transport should be systematically carried out in chemical transport models used to investigate stratospheric ozone. Furthermore, there is a great lack of available stratospheric ozone loss rates datasets ranging over the entire globe and over a large time period, other than computed by chemical models. This study shows that the applied methodology is a step toward filling that gap. Finally, a better understanding of the impact of climate change on stratospheric planetary wave activity and its potential repercussions on the ozone eddy mixing is required since eddy transport plays a significant role in the dynamics of the ozone hole.

REPORT SERIES of the MIT Joint Program on the Science and Policy of Global Change

1. **Uncertainty in Climate Change Policy Analysis**
Jacoby & Prinn December 1994
2. **Description and Validation of the MIT Version of the GISS 2D Model** *Sokolov & Stone* June 1995
3. **Responses of Primary Production and Carbon Storage to Changes in Climate and Atmospheric CO₂ Concentration** *Xiao et al.* October 1995
4. **Application of the Probabilistic Collocation Method for an Uncertainty Analysis** *Webster et al.* January 1996
5. **World Energy Consumption and CO₂ Emissions: 1950-2050** *Schmalensee et al.* April 1996
6. **The MIT Emission Prediction and Policy Analysis (EPPA) Model** *Yang et al.* May 1996 (*superseded* by No. 125)
7. **Integrated Global System Model for Climate Policy Analysis** *Prinn et al.* June 1996 (*superseded* by No. 124)
8. **Relative Roles of Changes in CO₂ and Climate to Equilibrium Responses of Net Primary Production and Carbon Storage** *Xiao et al.* June 1996
9. **CO₂ Emissions Limits: Economic Adjustments and the Distribution of Burdens** *Jacoby et al.* July 1997
10. **Modeling the Emissions of N₂O and CH₄ from the Terrestrial Biosphere to the Atmosphere** *Liu* Aug. 1996
11. **Global Warming Projections: Sensitivity to Deep Ocean Mixing** *Sokolov & Stone* September 1996
12. **Net Primary Production of Ecosystems in China and its Equilibrium Responses to Climate Changes**
Xiao et al. November 1996
13. **Greenhouse Policy Architectures and Institutions**
Schmalensee November 1996
14. **What Does Stabilizing Greenhouse Gas Concentrations Mean?** *Jacoby et al.* November 1996
15. **Economic Assessment of CO₂ Capture and Disposal**
Eckaus et al. December 1996
16. **What Drives Deforestation in the Brazilian Amazon?**
Pfaff December 1996
17. **A Flexible Climate Model For Use In Integrated Assessments** *Sokolov & Stone* March 1997
18. **Transient Climate Change and Potential Croplands of the World in the 21st Century** *Xiao et al.* May 1997
19. **Joint Implementation: Lessons from Title IV's Voluntary Compliance Programs** *Atkeson* June 1997
20. **Parameterization of Urban Subgrid Scale Processes in Global Atm. Chemistry Models** *Calbo et al.* July 1997
21. **Needed: A Realistic Strategy for Global Warming**
Jacoby, Prinn & Schmalensee August 1997
22. **Same Science, Differing Policies; The Saga of Global Climate Change** *Skolnikoff* August 1997
23. **Uncertainty in the Oceanic Heat and Carbon Uptake and their Impact on Climate Projections**
Sokolov et al. September 1997
24. **A Global Interactive Chemistry and Climate Model**
Wang, Prinn & Sokolov September 1997
25. **Interactions Among Emissions, Atmospheric Chemistry & Climate Change** *Wang & Prinn* Sept. 1997
26. **Necessary Conditions for Stabilization Agreements**
Yang & Jacoby October 1997
27. **Annex I Differentiation Proposals: Implications for Welfare, Equity and Policy** *Reiner & Jacoby* Oct. 1997
28. **Transient Climate Change and Net Ecosystem Production of the Terrestrial Biosphere**
Xiao et al. November 1997
29. **Analysis of CO₂ Emissions from Fossil Fuel in Korea: 1961-1994** *Choi* November 1997
30. **Uncertainty in Future Carbon Emissions: A Preliminary Exploration** *Webster* November 1997
31. **Beyond Emissions Paths: Rethinking the Climate Impacts of Emissions Protocols** *Webster & Reiner* November 1997
32. **Kyoto's Unfinished Business** *Jacoby et al.* June 1998
33. **Economic Development and the Structure of the Demand for Commercial Energy** *Judson et al.* April 1998
34. **Combined Effects of Anthropogenic Emissions and Resultant Climatic Changes on Atmospheric OH** *Wang & Prinn* April 1998
35. **Impact of Emissions, Chemistry, and Climate on Atmospheric Carbon Monoxide** *Wang & Prinn* April 1998
36. **Integrated Global System Model for Climate Policy Assessment: Feedbacks and Sensitivity Studies**
Prinn et al. June 1998
37. **Quantifying the Uncertainty in Climate Predictions**
Webster & Sokolov July 1998
38. **Sequential Climate Decisions Under Uncertainty: An Integrated Framework** *Valverde et al.* September 1998
39. **Uncertainty in Atmospheric CO₂ (Ocean Carbon Cycle Model Analysis)** *Holian* Oct. 1998 (*superseded* by No. 80)
40. **Analysis of Post-Kyoto CO₂ Emissions Trading Using Marginal Abatement Curves** *Ellerman & Decaux* Oct. 1998
41. **The Effects on Developing Countries of the Kyoto Protocol and CO₂ Emissions Trading**
Ellerman et al. November 1998
42. **Obstacles to Global CO₂ Trading: A Familiar Problem**
Ellerman November 1998
43. **The Uses and Misuses of Technology Development as a Component of Climate Policy** *Jacoby* November 1998
44. **Primary Aluminum Production: Climate Policy, Emissions and Costs** *Harnisch et al.* December 1998
45. **Multi-Gas Assessment of the Kyoto Protocol**
Reilly et al. January 1999
46. **From Science to Policy: The Science-Related Politics of Climate Change Policy in the U.S.** *Skolnikoff* January 1999
47. **Constraining Uncertainties in Climate Models Using Climate Change Detection Techniques**
Forest et al. April 1999
48. **Adjusting to Policy Expectations in Climate Change Modeling** *Shackley et al.* May 1999
49. **Toward a Useful Architecture for Climate Change Negotiations** *Jacoby et al.* May 1999
50. **A Study of the Effects of Natural Fertility, Weather and Productive Inputs in Chinese Agriculture**
Eckaus & Tso July 1999
51. **Japanese Nuclear Power and the Kyoto Agreement**
Babiker, Reilly & Ellerman August 1999
52. **Interactive Chemistry and Climate Models in Global Change Studies** *Wang & Prinn* September 1999
53. **Developing Country Effects of Kyoto-Type Emissions Restrictions** *Babiker & Jacoby* October 1999

Contact the Joint Program Office to request a copy. The Report Series is distributed at no charge.

REPORT SERIES of the MIT Joint Program on the Science and Policy of Global Change

54. **Model Estimates of the Mass Balance of the Greenland and Antarctic Ice Sheets** *Bugnion* Oct 1999
55. **Changes in Sea-Level Associated with Modifications of Ice Sheets over 21st Century** *Bugnion* October 1999
56. **The Kyoto Protocol and Developing Countries** *Babiker et al.* October 1999
57. **Can EPA Regulate Greenhouse Gases Before the Senate Ratifies the Kyoto Protocol?** *Bugnion & Reiner* November 1999
58. **Multiple Gas Control Under the Kyoto Agreement** *Reilly, Mayer & Harnisch* March 2000
59. **Supplementarity: An Invitation for Monopsony?** *Ellerman & Sue Wing* April 2000
60. **A Coupled Atmosphere-Ocean Model of Intermediate Complexity** *Kamenkovich et al.* May 2000
61. **Effects of Differentiating Climate Policy by Sector: A U.S. Example** *Babiker et al.* May 2000
62. **Constraining Climate Model Properties Using Optimal Fingerprint Detection Methods** *Forest et al.* May 2000
63. **Linking Local Air Pollution to Global Chemistry and Climate** *Mayer et al.* June 2000
64. **The Effects of Changing Consumption Patterns on the Costs of Emission Restrictions** *Lahiri et al.* Aug 2000
65. **Rethinking the Kyoto Emissions Targets** *Babiker & Eckaus* August 2000
66. **Fair Trade and Harmonization of Climate Change Policies in Europe** *Viguier* September 2000
67. **The Curious Role of "Learning" in Climate Policy: Should We Wait for More Data?** *Webster* October 2000
68. **How to Think About Human Influence on Climate** *Forest, Stone & Jacoby* October 2000
69. **Tradable Permits for Greenhouse Gas Emissions: A primer with reference to Europe** *Ellerman* Nov 2000
70. **Carbon Emissions and The Kyoto Commitment in the European Union** *Viguier et al.* February 2001
71. **The MIT Emissions Prediction and Policy Analysis Model: Revisions, Sensitivities and Results** *Babiker et al.* February 2001 (*superseded* by No. 125)
72. **Cap and Trade Policies in the Presence of Monopoly and Distortionary Taxation** *Fullerton & Metcalf* March '01
73. **Uncertainty Analysis of Global Climate Change Projections** *Webster et al.* Mar. '01 (*superseded* by No. 95)
74. **The Welfare Costs of Hybrid Carbon Policies in the European Union** *Babiker et al.* June 2001
75. **Feedbacks Affecting the Response of the Thermohaline Circulation to Increasing CO₂** *Kamenkovich et al.* July 2001
76. **CO₂ Abatement by Multi-fueled Electric Utilities: An Analysis Based on Japanese Data** *Ellerman & Tsukada* July 2001
77. **Comparing Greenhouse Gases** *Reilly et al.* July 2001
78. **Quantifying Uncertainties in Climate System Properties using Recent Climate Observations** *Forest et al.* July 2001
79. **Uncertainty in Emissions Projections for Climate Models** *Webster et al.* August 2001
80. **Uncertainty in Atmospheric CO₂ Predictions from a Global Ocean Carbon Cycle Model** *Holian et al.* September 2001
81. **A Comparison of the Behavior of AO GCMs in Transient Climate Change Experiments** *Sokolov et al.* December 2001
82. **The Evolution of a Climate Regime: Kyoto to Marrakech** *Babiker, Jacoby & Reiner* February 2002
83. **The "Safety Valve" and Climate Policy** *Jacoby & Ellerman* February 2002
84. **A Modeling Study on the Climate Impacts of Black Carbon Aerosols** *Wang* March 2002
85. **Tax Distortions and Global Climate Policy** *Babiker et al.* May 2002
86. **Incentive-based Approaches for Mitigating Greenhouse Gas Emissions: Issues and Prospects for India** *Gupta* June 2002
87. **Deep-Ocean Heat Uptake in an Ocean GCM with Idealized Geometry** *Huang, Stone & Hill* September 2002
88. **The Deep-Ocean Heat Uptake in Transient Climate Change** *Huang et al.* September 2002
89. **Representing Energy Technologies in Top-down Economic Models using Bottom-up Information** *McFarland et al.* October 2002
90. **Ozone Effects on Net Primary Production and Carbon Sequestration in the U.S. Using a Biogeochemistry Model** *Felzer et al.* November 2002
91. **Exclusionary Manipulation of Carbon Permit Markets: A Laboratory Test** *Carlén* November 2002
92. **An Issue of Permanence: Assessing the Effectiveness of Temporary Carbon Storage** *Herzog et al.* December 2002
93. **Is International Emissions Trading Always Beneficial?** *Babiker et al.* December 2002
94. **Modeling Non-CO₂ Greenhouse Gas Abatement** *Hyman et al.* December 2002
95. **Uncertainty Analysis of Climate Change and Policy Response** *Webster et al.* December 2002
96. **Market Power in International Carbon Emissions Trading: A Laboratory Test** *Carlén* January 2003
97. **Emissions Trading to Reduce Greenhouse Gas Emissions in the United States: The McCain-Lieberman Proposal** *Paltsev et al.* June 2003
98. **Russia's Role in the Kyoto Protocol** *Bernard et al.* Jun '03
99. **Thermohaline Circulation Stability: A Box Model Study** *Lucarini & Stone* June 2003
100. **Absolute vs. Intensity-Based Emissions Caps** *Ellerman & Sue Wing* July 2003
101. **Technology Detail in a Multi-Sector CGE Model: Transport Under Climate Policy** *Schafer & Jacoby* July 2003
102. **Induced Technical Change and the Cost of Climate Policy** *Sue Wing* September 2003
103. **Past and Future Effects of Ozone on Net Primary Production and Carbon Sequestration Using a Global Biogeochemical Model** *Felzer et al.* (revised) January 2004
104. **A Modeling Analysis of Methane Exchanges Between Alaskan Ecosystems and the Atmosphere** *Zhuang et al.* November 2003

Contact the Joint Program Office to request a copy. The Report Series is distributed at no charge.

REPORT SERIES of the MIT Joint Program on the Science and Policy of Global Change

105. **Analysis of Strategies of Companies under Carbon Constraint** Hashimoto January 2004
106. **Climate Prediction: The Limits of Ocean Models** Stone February 2004
107. **Informing Climate Policy Given Incommensurable Benefits Estimates** Jacoby February 2004
108. **Methane Fluxes Between Terrestrial Ecosystems and the Atmosphere at High Latitudes During the Past Century** Zhuang et al. March 2004
109. **Sensitivity of Climate to Diapycnal Diffusivity in the Ocean** Dalan et al. May 2004
110. **Stabilization and Global Climate Policy** Sarofim et al. July 2004
111. **Technology and Technical Change in the MIT EPPA Model** Jacoby et al. July 2004
112. **The Cost of Kyoto Protocol Targets: The Case of Japan** Paltsev et al. July 2004
113. **Economic Benefits of Air Pollution Regulation in the USA: An Integrated Approach** Yang et al. (revised) Jan. 2005
114. **The Role of Non-CO₂ Greenhouse Gases in Climate Policy: Analysis Using the MIT IGSM** Reilly et al. Aug. '04
115. **Future U.S. Energy Security Concerns** Deutch Sep. '04
116. **Explaining Long-Run Changes in the Energy Intensity of the U.S. Economy** Sue Wing Sept. 2004
117. **Modeling the Transport Sector: The Role of Existing Fuel Taxes in Climate Policy** Paltsev et al. November 2004
118. **Effects of Air Pollution Control on Climate** Prinn et al. January 2005
119. **Does Model Sensitivity to Changes in CO₂ Provide a Measure of Sensitivity to the Forcing of Different Nature?** Sokolov March 2005
120. **What Should the Government Do To Encourage Technical Change in the Energy Sector?** Deutch May '05
121. **Climate Change Taxes and Energy Efficiency in Japan** Kasahara et al. May 2005
122. **A 3D Ocean-Seaice-Carbon Cycle Model and its Coupling to a 2D Atmospheric Model: Uses in Climate Change Studies** Dutkiewicz et al. (revised) November 2005
123. **Simulating the Spatial Distribution of Population and Emissions to 2100** Asadoorian May 2005
124. **MIT Integrated Global System Model (IGSM) Version 2: Model Description and Baseline Evaluation** Sokolov et al. July 2005
125. **The MIT Emissions Prediction and Policy Analysis (EPPA) Model: Version 4** Paltsev et al. August 2005
126. **Estimated PDFs of Climate System Properties Including Natural and Anthropogenic Forcings** Forest et al. September 2005
127. **An Analysis of the European Emission Trading Scheme** Reilly & Paltsev October 2005
128. **Evaluating the Use of Ocean Models of Different Complexity in Climate Change Studies** Sokolov et al. November 2005
129. **Future Carbon Regulations and Current Investments in Alternative Coal-Fired Power Plant Designs** Sekar et al. December 2005
130. **Absolute vs. Intensity Limits for CO₂ Emission Control: Performance Under Uncertainty** Sue Wing et al. January 2006
131. **The Economic Impacts of Climate Change: Evidence from Agricultural Profits and Random Fluctuations in Weather** Deschenes & Greenstone January 2006
132. **The Value of Emissions Trading** Webster et al. Feb. 2006
133. **Estimating Probability Distributions from Complex Models with Bifurcations: The Case of Ocean Circulation Collapse** Webster et al. March 2006
134. **Directed Technical Change and Climate Policy** Otto et al. April 2006
135. **Modeling Climate Feedbacks to Energy Demand: The Case of China** Asadoorian et al. June 2006
136. **Bringing Transportation into a Cap-and-Trade Regime** Ellerman, Jacoby & Zimmerman June 2006
137. **Unemployment Effects of Climate Policy** Babiker & Eckaus July 2006
138. **Energy Conservation in the United States: Understanding its Role in Climate Policy** Metcalf Aug. '06
139. **Directed Technical Change and the Adoption of CO₂ Abatement Technology: The Case of CO₂ Capture and Storage** Otto & Reilly August 2006
140. **The Allocation of European Union Allowances: Lessons, Unifying Themes and General Principles** Buchner et al. October 2006

REPORT SERIES of the MIT Joint Program on the Science and Policy of Global Change

154. **Modeling the Prospects for Hydrogen Powered Transportation Through 2100** *Sandoval et al.* February 2008
155. **Potential Land Use Implications of a Global Biofuels Industry** *Gurgel et al.* March 2008
156. **Estimating the Economic Cost of Sea-Level Rise** *Sugiyama et al.* April 2008
157. **Constraining Climate Model Parameters from Observed 20th Century Changes** *Forest et al.* April 2008
158. **Analysis of the Coal Sector under Carbon Constraints** *McFarland et al.* April 2008
159. **Impact of Sulfur and Carbonaceous Emissions from International Shipping on Aerosol Distributions and Direct Radiative Forcing** *Wang & Kim* April 2008
160. **Analysis of U.S. Greenhouse Gas Tax Proposals** *Metcalfe et al.* April 2008
161. **A Forward Looking Version of the MIT Emissions Prediction and Policy Analysis (EPPA) Model** *Babiker et al.* May 2008
162. **The European Carbon Market in Action: Lessons from the first trading period** Interim Report *Convery, Ellerman, & de Perthuis* June 2008
163. **The Influence on Climate Change of Differing Scenarios for Future Development Analyzed Using the MIT Integrated Global System Model** *Prinn et al.* September 2008
164. **Marginal Abatement Costs and Marginal Welfare Costs for Greenhouse Gas Emissions Reductions: Results from the EPPA Model** *Holak et al.* November 2008
165. **Uncertainty in Greenhouse Emissions and Costs of Atmospheric Stabilization** *Webster et al.* November 2008
166. **Sensitivity of Climate Change Projections to Uncertainties in the Estimates of Observed Changes in Deep-Ocean Heat Content** *Sokolov et al.* November 2008
167. **Sharing the Burden of GHG Reductions** *Jacoby et al.* November 2008
168. **Unintended Environmental Consequences of a Global Biofuels Program** *Melillo et al.* January 2009
169. **Probabilistic Forecast for 21st Century Climate Based on Uncertainties in Emissions (without Policy) and Climate Parameters** *Sokolov et al.* January 2009
170. **The EU's Emissions Trading Scheme: A Proto-type Global System?** *Ellerman* February 2009
171. **Designing a U.S. Market for CO₂** *Parsons et al.* February 2009
172. **Prospects for Plug-in Hybrid Electric Vehicles in the United States & Japan: A General Equilibrium Analysis** *Karplus et al.* April 2009
173. **The Cost of Climate Policy in the United States** *Paltsev et al.* April 2009
174. **A Semi-Empirical Representation of the Temporal Variation of Total Greenhouse Gas Levels Expressed as Equivalent Levels of Carbon Dioxide** *Huang et al.* June 2009
175. **Potential Climatic Impacts and Reliability of Very Large Scale Wind Farms** *Wang & Prinn* June 2009
176. **Biofuels, Climate Policy and the European Vehicle Fleet** *Gitiaux et al.* August 2009
177. **Global Health and Economic Impacts of Future Ozone Pollution** *Selin et al.* August 2009
178. **Measuring Welfare Loss Caused by Air Pollution in Europe: A CGE Analysis** *Nam et al.* August 2009
179. **Assessing Evapotranspiration Estimates from the Global Soil Wetness Project Phase 2 (GSWP-2) Simulations** *Schlosser and Gao* September 2009
180. **Analysis of Climate Policy Targets under Uncertainty** *Webster et al.* September 2009
181. **Development of a Fast and Detailed Model of Urban-Scale Chemical and Physical Processing** *Cohen & Prinn* October 2009
182. **Distributional Impacts of a U.S. Greenhouse Gas Policy: A General Equilibrium Analysis of Carbon Pricing** *Rausch et al.* November 2009
183. **Canada's Bitumen Industry Under CO₂ Constraints** *Chan et al.* January 2010
184. **Will Border Carbon Adjustments Work?** *Winchester et al.* February 2010
185. **Distributional Implications of Alternative U.S. Greenhouse Gas Control Measures** *Rausch et al.* June 2010
186. **The Future of U.S. Natural Gas Production, Use, and Trade** *Paltsev et al.* June 2010
187. **Combining a Renewable Portfolio Standard with a Cap-and-Trade Policy: A General Equilibrium Analysis** *Morris et al.* July 2010
188. **On the Correlation between Forcing and Climate Sensitivity** *Sokolov* August 2010
